### Big Icy Moon of Jupiter Found to Have a 'Voice' After All; Europa Flyby Next for Galileo

Jupiter's big moon [Ganymede](#) is not only the size of a planet -- it sounds like one too, as heard in audio recordings made from data returned by NASA's Galileo spacecraft released today.

*Plasma Wave "Sounds" From Ganymede*

Characterized by a soaring whistle and hissing static, [Ganymede's song](#) reveals that the Solar System's largest moon is also the only one known to possess a planet-like, self-generated magnetic cocoon called a [magnetosphere](#), which shields the moon from the magnetic influence of its giant parent body, Jupiter.

Published in the scientific journal Nature this week, these new Galileo findings and other measurements from several Galileo sensors were presented today in a news briefing held at NASA's Jet Propulsion Laboratory (JPL), Pasadena, CA. Taken together, scientists say the new Ganymede findings are painting a portrait of a body that from the inside out closely resembles a planet like Earth rather than other moons in the Solar System.

"The data we get back is in the form of a spectrogram, and reading it is kind of like looking at a musical score," said Dr. Donald Gurnett, University of Iowa physicist and principal investigator on Galileo's plasma wave instrument. It was his experiment that first detected the telltale signals of a magnetosphere during the spacecraft's close flybys of that moon on June 27 and Sept. 6.

Gurnett said the unique pattern of frequencies his instrument detected is characteristic of a magnetosphere and closely matches his previous studies of the magnetospheres of Earth, Saturn and Jupiter. "The instant I saw the spectrogram, I could tell we had passed through a magnetosphere at Ganymede," Gurnett said.

Describing the electromagnetic wave activity that his experiment detected at Ganymede, Gurnett said the approach to the large moon was relatively quiet, "until all of a sudden, there's a big burst of noise that signals the entry into Ganymede's magnetosphere. Then, for about 50 minutes, we detected the kinds of noises that are typical of a passage through a magnetosphere. As we exited the magnetosphere, there was another big burst of noise."

Gurnett checked with Dr. Margaret Kivelson of the University of California at Los Angeles (UCLA), principal investigator for the magnetometer experiment on the spacecraft. Kivelson confirmed the detection of a large increase in magnetic field strength near Ganymede. Related data from the two close flybys have confirmed that Ganymede has a magnetic field of its own.

Using extremely precise data from tracking the spacecraft, investigators on Galileo's celestial mechanics team also have been able to confirm that Ganymede's interior is differentiated, probably having a three-layer structure. "These data show clearly that Ganymede has differentiated into a core and mantle, which is in turn enclosed by an ice shell," said JPL planetary scientist Dr. John Anderson, team leader on the Galileo radio science experiment.

"Combined with the discovery of an intrinsic magnetic field, our gravity results indicate that Ganymede has a metallic core about 250 to 800 miles in," said Anderson. "This is surrounded by a rocky silicate mantle, which is in turn enclosed by an ice shell about 500 miles thick. Depending on whether the core is pure iron or an alloy of iron and iron sulfide, it could account for as little as 1.4 percent or as much as one-third of the total mass of Ganymede."

This differentiated structure is the most likely cause of Ganymede's newly discovered magnetic field, which in turn gives rise to the magnetosphere, reported UCLA geophysicist Dr. Gerald Schubert, an interdisciplinary investigator on Galileo's science team. Scientists suspect Ganymede's magnetic field is generated the same way as Earth's, through the dynamo action of the fluid mantle rotating above a metallic core. The only other solid bodies in the Solar System known to have magnetic fields are Mercury, Earth and possibly Jupiter's volcanic moon Io.

"At Ganymede, the magnetic field is strong enough to carve out a magnetosphere with clearly defined boundaries within Jupiter's magnetosphere, making it the only 'magnetosphere within a magnetosphere' known in the Solar System," Kivelson said.

The strong magnetic characteristics of Ganymede, in combination with its residence within Jupiter's powerful magnetosphere, make the Jovian environment even more intriguing, said Galileo project scientists Dr. Torrence V. Johnson. "The physics taking place within Jupiter's magnetosphere are of great interest to scientists attempting to understand the complex interplay of magnetic forces and matter throughout the universe," he said.

***New Galileo Images of Callisto***

Newly received Galileo images of Jupiter's moon [Callisto](#) and one of [Europa](#) also were released at the briefing. Scientists were surprised by the lack of small craters visible in the images. Some small craters appear to have been softened or modified by downslope movement of debris, revealing ice-rich surfaces.

Galileo's next moon encounter occurs December 18-19, when the spacecraft makes its first close approach to Europa, the moon thought to harbor a liquid ocean beneath its icy surface. Results from that flyby will be radioed to Earth starting in the last half of December through early February.

***New Galileo Image of Europa***

The Europa image received from the spacecraft earlier this week shows the cracked surface of this moon in greater detail than it has been seen before. The new image shows an area 150 miles by 140 miles that has been highly disrupted by fractures and ridges.

Arizona State University planetary scientist Dr. Kelly Bender of Galileo's imaging team said that symmetric ridges in the dark bands suggest that Europa's surface crust was separated and filled with darker material, somewhat analogous to spreading centers in the ocean basins of Earth. Although some impact craters are visible, their general absence indicates a youthful surface, she said.

The youngest ridges, such as the two features that cross the center of the picture, have central fractures, aligned knobs, and irregular dark patches. These and other features could indicate cryovolcanism, or processes related to eruption of ice and gases.

Galileo was launched in 1989 and entered orbit around Jupiter Dec. 7, 1995. The Galileo mission is managed by JPL for NASA's Office of Space Science, Washington, DC.
